# Presentation Outline

---

## TODAY'S TOPICS

- Normal haemoglobin (a senseless act of beauty)
- Sickle haemoglobin a survival advantage for malaria
- Adaptive responses
- Understanding sickle cell disease SSD
- The clinical presentations of SSD
- The treatment options in SSD
- The transfusion strategies in SSD simple and exchange transfusion and making a difference
- The importance of red cell antigen matching and the prevention of alloimmunisation
- The current impact of substituting O D (-) on O D (-) inventory management
- Future options for sustainability

## Pathophysiology

The vessel blockage is responsible for vasoocclusion

This impairs blood flow and prevents effective delivery of oxygen to the tissues

This is the underlying cause for painful crises (acute) and chronic damage to potentially every organ in the body

Brain damage is stroke and disability

Acute chest syndrome leads to pulmonary fibrosis and hypertension

Kidney damage leads to renal failure

Splenic infarction leads to hyposplenism (non functioning spleen) and life long susceptibility to infection and sepsis

Avascular (no blood supply) necrosis of the hips and chronic leg ulceration (reduced blood flow) are common complications

There are increased risks for pregnancy and child birth

IBTS

## Clinical course and survival

Significant morbidity and mortality

Variable in severity and onset of acute and chronic complications is unpredictable

This uncertainty is increasingly recognised as having adverse psychological consequences and social disruption for the patient and family

As recently as 1970s patient not expected to survive to adulthood (UK)

2020...99% children survive to adulthood (Ireland)

Median survival for sickle cell anaemia (UK) mid forties

Irish sickle cell anaemia population not matured

NCEPOD (2008) listed stroke disease, multi-organ failure and acute chest syndrome as most common causes of death

Aim of transfusion therapy and choice of modalities	Comment
Increase oxygen carrying capacity	Sickle cell anaemia patients typically have a haemoglobin 6.0-8.0 g/dl Simple additive transfusion (top up) (2-3 units) is indicated when the primary reason for acute transfusion is severe anaemia
Decrease haemoglobin S percentage	Target reduction is < 30% and this will decrease vaso occlusion Exchange transfusion is deployed (remove patient blood replace with donor blood) (3-6 units)
Long term automated transfusion programmes for control of haemoglobin S percentage (prevention of stroke disease)	Automated exchange transfusion every four weeks (8-10 units)

IBTS

Selection of blood and component	Comment
ABO compatible	
D Cc Ee K compatible	This is to prevent the formation of red cell antibodies and has been recommended since 2004
Allo immunised (formed red cell antibodies)	Red cells negative for corresponding antigens
Perform extended phenotype as a base line	C c E e K k Jka Jkb Fya Fyb M N S s (U)
Perform genotype	This is important because of variant expression of CcEe in African ancestry and non ethnically matched donors will alloimmunise
Hyper haemolytic transfusion reactions	Poorly understood serious complication of red cell transfusion....the patient will haemolyse transfused and own red blood cells and antibody may not be detected on testing

## Alloimmunisation

47% of SSD have at least one red cell antibody

Risk per red cell component transfused = 3.1%

Anti K E C Jk account for 80%

17% have > 4 red cell antibodies

10% have positive DAT (autoantibodies)

Attributable to genetic differences in red cell antigens expressed in donor and recipient populations

Prophylactic matching E C K reduces alloimmunisation rate from 3% to 0.5% per red cell component in children

# Alloimmunisation

- Up to 48% in patients with SCD<sup>1</sup>
- C, E, K, Fy<sup>a</sup>, Ik<sup>b</sup>, S higher incidence than Caucasians
  - 2/3 Antibodies anti C, E, K
  - C,E, K matching
    - Reduced rate of allo-immunisation from 1.7-3.9 AB/100 units transfused to 0.26-0.5.
- Racially matched units
  - Reduced anti Ik, Fy and S antibodies
  - Rh allo-immunisation rate remains high

## High prevalence of red cell alloimmunisation in SCD despite ethnic matching donors

African American donors matched for D C E K (n=182 patients)

58% chronic and 15% episodic transfused patients alloimmunised

45% chronic and 12% episodic transfused patients Rh immunised

N=146 red cell antibodies, 91 unexplained Rh (28% associated haemolytic transfusion reactions)

High resolution genotyping confirmed variant alleles in 87%

Adapted protocols C- to C + patient variant C; D - to patient D+ genotype predict partial D....downside is disparate Jk<sup>b</sup> Fy<sup>a</sup> S in Caucasian D- donor

There is a need for clinical trials
